A Quantitative Framework to Assess the Risk- Reward Profile of Non-Equity Products

**AUTHOR
MARCELLO MINENNA**

CONTRIBUTORS: GIOVANNA MARIA
BOI, PAOLO VERZELLA, ANTONIO
RUSSO, MARIO ROMEO AND DIEGO
MONORCHIO

"This book fills the gap that exists between the risk management tools available to industry insiders, and those available to investors. It is a welcome contribution that will be helpful to anyone who needs to assess the risk of non-equity products."

Jaksa Cvitanic, Professor of Mathematical Finance, Caltech

"Rigor and clarity characterize this methodology to assess the risk of every non-equity product. Well established stochastic techniques are applied in an original way to convey the key information on the time horizon, the degree of risk, the costs and potential returns of the investment and therefore to match the investor's preferences in terms of liquidity attitude, risk taking, desired returns and acceptable losses."

Prof. Svetlozar Rachev, Department of Statistics and Applied Probability, University of California at Santa Barbara

"I warmly welcome the publication of this book which describes a probabilistic framework for risk evaluation. The specific aim is that of providing financial institutions and regulators with tools and techniques for an objective and clear representation of key investor information. This shall help in orientating buyers through the difficult path of non-equity products selection."

Prof. Francesco Corielli, Department of Finance, Bocconi University

"This book constitutes an excellent collection of quantitative methods to the measurement and representation of the risks of non-equity products that comes from a simple but also winning intuition: the information needs of retail investors are not really different from those of financial institutions since they both want the upside gain by trying to contain the downside risk."

Prof. Hélyette Geman, School of Business, Economics and Informatics, Birkbeck, University of London

"This important book establishes a benchmark for a future financial regulation based on quantitative techniques. At the same time it casts a serious challenge to the financial industry on the need of quantitative disclosure, that will be the future of the financial system worldwide. Hope the challenge will be accepted."

Prof. Umberto Cherubini, Department of Mathematical Economics, University of Bologna

"This book contains a valid quantitative methodology to shed light on the risks embedded in any non-equity product. By answering the key questions of any investor about the potential performances, the risk rating and the optimal holding time of the product, the three "pillars" of the book are the best candidates to definitely remove the informative lack that worldwide regulators have recognized in the existing rules on risks disclosure. The adoption of these "pillars" would be the ideal completion of the regulatory reform undertaken by the European Authorities regarding the revision of the information contents for Packaged Retail Investment Products. Should the quantitative framework set forth in this work become the reference to update the regulatory framework on transparency, an authentic reversal of the traditional approaches to risks transparency would be realized with effective benefits for investors' comprehension and for allowing them to pick the product that best fits their needs."

Prof. Riccardo Cesari, Professor of Mathematical Methods for Economic and Financial Sciences, University of Bologna

"This innovative book sheds a light on the dark path of the financial risks intrinsic to non-equity financial products, which are often underestimated, or even poorly understood, by investors seeking higher returns. Mathematical finance techniques are here applied in an original and unconventional manner for the purpose of effectively disclosing these risks and properly assessing their impact on investments' returns."

Fabio Mercurio, Head of Quant Business Managers at Bloomberg LP and adjunct professor at NYU

Syllabus

- Preliminaries: the three pillars
- The recommended Investment horizon
- Synthetic risk indicator
- Unbundling and Probabilistic performance scenarios
- An Application of the methodology

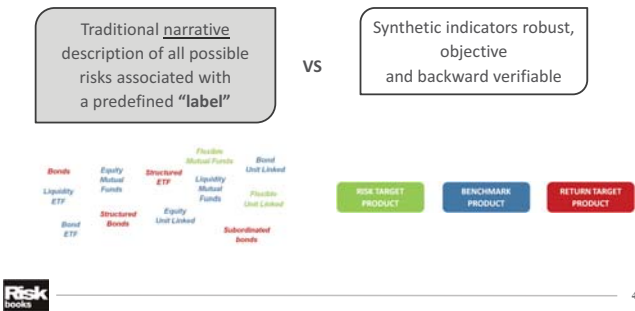

Preliminaries

Non-equity Investment products should be classified according to their financial characteristics and not by “labels” assigned by the issuer or by the regulatory framework.

Preliminaries

The book offers an approach for the transparency of the risk profile of non-equity products that is based on synthetic indicators – defined through specific quantitative methods – in order to allow investors to take informed investment decisions.

Preliminaries

Preliminaries

These metrics provide a guide to investors in the interpretation of complex information conveyed in the offering document, supporting the decision process by means of a sequential filtering procedure:

Syllabus

- Preliminaries: the three pillars
- The recommended Investment horizon
- Synthetic risk indicator
- Unbundling and Probabilistic performance scenarios
- An Application of the methodology

The recommended Investment horizon

The recommended Investment horizon

The recommended investment time horizon

The event to study from a probabilistic point of view is related to possible exit strategies after having recovered all the costs of the product :

The investment recovers the initial costs and off-sets the running costs at least once

that can be calculated through the concept of
First Passage Time

The recommended Investment horizon

First Passage Time:
First time (expressed in years) such that the value of the Invested Capital (CI) recovers the initial costs and off-sets the running costs.

The recommended Investment horizon

First Passage Time:
First time (expressed in years) such that the value of the Invested Capital (CI) recovers the initial costs and off-sets the running costs.

The recommended Investment horizon

The probability of the event:

The investment recovers the initial costs and off-sets the running costs at least once

given a confidence level α , uniquely identifies a time T^* on the cumulative distribution function of the first passage times, i.e.:

$$T^* = \left\{ T \in \mathbb{R}^+ : P[t^* \leq T] = \alpha \right\}$$

where

$$t^* = \inf \left[t \in \mathbb{R}^+ : CI_t > CN \right]$$

is the first passage time

The recommended Investment horizon

1. Calculation of the probability distribution of the first passage times:

The recommended Investment horizon

2. Derivation of the cumulative distribution function of the first passage times:

The recommended Investment horizon

3. The confidence level α uniquely identifies T^* on the cumulative distribution function of the first passage times:

The recommended Investment horizon

When many probability distribution functions are considered, letting varying volatilities and costs, the problem of correctly identifying a set of minimum thresholds arises:

The recommended Investment horizon

Anyway, the recommended minimum investment time horizon...

$$T^* = \left\{ T \in \mathbb{R}^+ : P[t^* \leq T] = \alpha \right\}$$

.... Must be coherent with the principle

+ VOLATILITY + TIME HORIZON

The correct way to solve the problem is to set up an operative procedure to select properly each threshold according to the above principle

The recommended Investment horizon

Connection between probability, volatility and costs

First passage times for the break-even barrier are monitored at infinitesimal time intervals:

$dt \rightarrow 0$

$$T^* = \left\{ T \in \mathbb{R}^+ : P[t^* \leq T] = \alpha \right\}$$

$$P[t^* \leq T] = N\left(d_2\left(\frac{CI_0}{CN}\right)\right) + \left(\frac{CN}{CI_0}\right)^{\frac{2(\bar{r}-cr)}{\sigma^2}-1} \cdot N\left(-d_2\left(\frac{CN}{CI_0}\right)\right)$$

$$d_2(x) = \frac{\log x + \left(\bar{r} - cr - \frac{1}{2}\sigma^2\right)T}{\sigma\sqrt{T}}$$

$$N(x) = \int_{-\infty}^x \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}z^2} dz$$

The recommended Investment horizon

Connection between probability, volatility and costs

Asymptotic properties: $T \rightarrow \infty$

cr : recurrent costs as a fixed %

$$\lim_{T \rightarrow \infty} P[t^* \leq T] = \begin{cases} 1 & \text{if } (\bar{r} - cr) \geq \frac{1}{2}\sigma^2 \\ \left(\frac{CN}{CI_0}\right)^{\frac{2(\bar{r}-cr)}{\sigma^2}-1} & \text{if } (\bar{r} - cr) < \frac{1}{2}\sigma^2 \end{cases}$$

The recommended Investment horizon

Connection between probability, volatility and costs

Under our assumptions:

$$\lim_{T \rightarrow \infty} \mathbb{P}[t^* \leq T] = \begin{cases} 1 & \text{if } (\bar{r} - cr) \geq \frac{1}{2} \sigma^2 \\ \left(\frac{CN}{CI_0} \right)^{\frac{2(\bar{r}-cr)}{\sigma^2} - 1} & \text{if } (\bar{r} - cr) < \frac{1}{2} \sigma^2 \end{cases}$$

For a given level of costs, it is possible to analytically derive the connection between volatility and time horizon

The recommended Investment horizon

Connection between probability, volatility and costs

$$T \rightarrow \infty, dt \rightarrow 0$$

$$\frac{dP}{d\sigma} = \left(-4 \frac{(\bar{r} - cr)}{\sigma^3} \ln \left(\frac{CN}{CI_0} \right) \left(\frac{CN}{CI_0} \right)^{\frac{2(\bar{r}-cr)}{\sigma^2} - 1} \right)$$

FIRST ORDER SENSITIVITY ANALYSIS

FIRST ORDER ASYMPTOTIC CONDITION

The recommended Investment horizon

Connection between probability, volatility and costs

$$T \rightarrow \infty, dt \rightarrow 0$$

$$\frac{dP}{d\sigma} = \left(-4 \frac{(\bar{r} - cr)}{\sigma^3} \ln \left(\frac{CN}{CI_0} \right) \left(\frac{CN}{CI_0} \right)^{\frac{2(\bar{r}-cr)}{\sigma^2} - 1} \right)$$

1. $(\bar{r} - cr) > 0 \Leftrightarrow \frac{dP}{d\sigma} < 0$
2. $(\bar{r} - cr) \leq 0 \Leftrightarrow \frac{dP}{d\sigma} \geq 0$

The existence of two alternative states of nature requires to verify whether both of them make sense in financial terms under the risk-neutral measure.

The recommended Investment horizon

Connection between probability, volatility and costs

$$T \rightarrow \infty, dt \rightarrow 0$$

$$\frac{dP}{d\sigma} = \left(-4 \frac{\bar{r}}{\sigma^3} \ln \left(\frac{CN}{CI_0} \right) \left(\frac{CN}{CI_0} \right)^{\frac{2\bar{r}}{\sigma^2} - 1} \right)$$

1. $\bar{r} > 0 \Leftrightarrow \frac{dP}{d\sigma} < 0$
2. $\bar{r} \leq 0 \Leftrightarrow \frac{dP}{d\sigma} \geq 0$

$cr = 0$

Being running costs a specific feature of any financial product they would interfere with the task of identifying which of the two conditions has a sound financial meaning. Therefore, they will be temporarily neglected.

The recommended Investment horizon

Connection between probability, volatility and costs

$$T \rightarrow \infty, dt \rightarrow 0$$

$$\frac{dP}{d\sigma} = \left(-4 \frac{\bar{r}}{\sigma^3} \ln \left(\frac{CN}{CI_0} \right) \left(\frac{CN}{CI_0} \right)^{\frac{2\bar{r}}{\sigma^2} - 1} \right)$$

1. $\bar{r} > 0 \Leftrightarrow \frac{dP}{d\sigma} < 0$
2. $\bar{r} \leq 0 \Leftrightarrow \frac{dP}{d\sigma} \geq 0$

$cr = 0$

Since it is safe to assume a positive interest rate r in financial markets, only condition 1. correctly captures the connection between volatility and time horizon.

The recommended Investment horizon

Connection between probability, volatility and costs

$$T \rightarrow \infty, dt \rightarrow 0$$

$$\frac{dP}{d\sigma} = \left(-4 \frac{\bar{r}}{\sigma^3} \ln \left(\frac{CN}{CI_0} \right) \left(\frac{CN}{CI_0} \right)^{\frac{2\bar{r}}{\sigma^2} - 1} \right)$$

1. $\bar{r} > 0 \Leftrightarrow \frac{dP}{d\sigma} < 0$
2. $\bar{r} \leq 0 \Leftrightarrow \frac{dP}{d\sigma} \geq 0$

$cr = 0$

As $T \rightarrow \infty$ condition 1. implies that the cumulative distribution function P is a strictly decreasing function of the volatility, i.e.:

$$\forall \sigma_i, \sigma_j \in \mathbb{R}^+, \sigma_j > \sigma_i \Rightarrow P(\sigma_j) < P(\sigma_i)$$

The recommended Investment horizon

Connection between probability, volatility and costs

$$T \rightarrow \infty, dt \rightarrow 0$$

$$\frac{dP}{d\sigma} = \left(-4 \frac{\bar{r}}{\sigma^3} \ln \left(\frac{CN}{CI_0} \right) \left(\frac{CN}{CI_0} \right)^{\frac{2\bar{r}}{\sigma^2}-1} \right)$$

1. $\bar{r} > 0 \Leftrightarrow \frac{dP}{d\sigma} < 0$

2. $\bar{r} \leq 0 \Leftrightarrow \frac{dP}{d\sigma} \geq 0$

$cr = 0$

In other words, for a given a confidence level, as the volatility grows, the recommended investment time horizon increases as well:

+VOLATILITY + RECOMMENDED INVESTMENT TIME HORIZON

The recommended Investment horizon

Connection between probability, volatility and costs

$$T \rightarrow \infty, dt \rightarrow 0$$

$$\frac{d^2P}{d\sigma^2} = \frac{4}{\sigma^4} (\bar{r} - cr) \ln \left(\frac{CN}{CI_0} \right) \left(\frac{CN}{CI_0} \right)^{\frac{2(\bar{r}-cr)}{\sigma^2}-1} \cdot \left[1 + \frac{4(\bar{r}-cr)}{\sigma^2} \ln \left(\frac{CN}{CI_0} \right) \right]$$

$(\bar{r} - cr) > 0 \Rightarrow \frac{d^2P}{d\sigma^2} > 0$

➡

SECOND ORDER ASYMPTOTIC CONDITION

Second Order Sensitivity Analysis

The recommended Investment horizon

Connection between probability, volatility and costs

$$T \rightarrow \infty, dt \rightarrow 0$$

1. $(\bar{r} - cr) > 0 \Leftrightarrow \frac{dP}{d\sigma} < 0$

$(\bar{r} - cr) > 0 \Rightarrow \frac{d^2P}{d\sigma^2} > 0$

$\exists T^* \in [0, \infty[: \frac{dP}{d\sigma} = 0$

2. $(\bar{r} - cr) \leq 0 \Leftrightarrow \frac{dP}{d\sigma} \geq 0$

Summarizing the results of the asymptotic analysis in continuous time:

- As $T \rightarrow \infty$, for given a confidence level, more volatility implies a larger recommended investment time horizon
- It is always possible to find a minimum and finite time T^* , beyond which the strong condition

+VOLATILITY + RECOMMENDED INVESTMENT TIME HORIZON holds

The recommended Investment horizon

DETERMINATION OF THE INVESTMENT TIME HORIZON

$T \rightarrow \infty$
 $dt \rightarrow 0$
 $P(\infty, \sigma)$

1. $(\bar{r} - cr) > 0 \Leftrightarrow \frac{dP}{d\sigma} < 0$

$(\bar{r} - cr) > 0 \Rightarrow \frac{d^2P}{d\sigma^2} > 0$

⇒

General Framework:

T finite
 $dt \rightarrow 0$
 $P(T, \sigma)$

$(\bar{r} - cr) > 0 \Leftrightarrow \lim_{T \rightarrow \infty} \frac{\partial P(T, \sigma)}{\partial \sigma} < 0$

$(\bar{r} - cr) > 0 \Rightarrow \lim_{T \rightarrow \infty} \frac{\partial^2 P(T, \sigma)}{\partial \sigma^2} > 0$

Everything shown above also holds with T finite!

- Unbundling and Probabilistic performance scenarios
- An Application of the methodology

Synthetic risk indicator

Synthetic risk indicator

Volatility is the most immediate risk measure and it has a one-to-one relationship with whatever loss measure (VaR, ES, etc.)

Synthetic risk indicator

e.g. : geometric brownian motion

$$dS_t = rS_t dt + \sigma S_t dW_t$$

$$VaR_{\alpha, 1 year} = e^{\sigma \Phi^{-1}(\alpha) + \left(r - \frac{\sigma^2}{2}\right) - 1}$$

$$ES_{\alpha, 1 year} = \frac{1}{\alpha} e^{\sigma \Phi^{-1}(\alpha) + \left(r - \frac{\sigma^2}{2}\right) - 1}$$

Synthetic risk indicator

EXAMPLES

Synthetic risk indicator

Synthetic risk indicator

Synthetic risk indicator

Synthetic risk indicator

Synthetic risk indicator

Synthetic risk indicator

The assignment of the degree of risk is made according to a quantitative criterion that maps coherently any volatility interval into a corresponding qualitative risk class

Risk books

Synthetic risk indicator

Synthetic risk indicator

Synthetic risk indicator

Synthetic risk indicator

Volatility intervals have to be suitably calibrated
in order to avoid wrong risk representations

Synthetic risk indicator

Volatility intervals have to be suitably calibrated
in order to avoid wrong risk representations

THE ISSUE

Defining suitable requirements to partition the
volatility space $[0, +\infty)$ into an optimal number n^* of
subsequent intervals with optima extrema

Synthetic risk indicator

Volatility intervals have to be suitably calibrated
in order to avoid wrong risk representations

Requirement n.1
the **optimal grid** of volatility intervals
has to be **consistent** with the **principle**:

+ RISK + LOSSES

**VOLATILITY INTERVALS MUST HAVE
AN INCREASING WIDTH IN ABSOLUTE TERMS**

Synthetic risk indicator

Volatility intervals have to be suitably calibrated
in order to avoid wrong risk representations

Requirement n.2
the optimal grid of volatility intervals must be
market feasible

**REALIZED VOLATILITY CONSISTENT WITH MARKET
EXPECTATIONS OF FUTURE VOLATILITY**
(UNLESS FOR SIGNIFICANT SUDDEN SHOCKS)

Synthetic risk indicator

Realized volatility

Any product on the markets reflects specific/different
asset management policies

Historical data can be "dirty"

1st INTUITION

It has to be studied a theoretical product
managed by an automatic asset manager
who has a specific risk budget,
identified by a given volatility interval

Synthetic risk indicator

1st INTUITION

AUTOMATIC ASSET MANAGER:

described by a stochastic volatility model with:

- mean reversion
- symmetry w.r.t. to a given risk budget
- ex ante minimization of the migration risk

$$dS_t = rS_t dt + \sigma_t S_t dW_t^{(1)}$$

$$d\sigma_t^2 = \kappa(\theta - \sigma_t^2)dt + v_t \sigma_t dW_t^{(2)}$$

Synthetic risk indicator

Market expectations of future volatility

future volatility is predicted by exploiting information embedded in recently observed data

2nd INTUITION

Market expectation is given by volatility prediction intervals based on proper diffusive models

Synthetic risk indicator

2nd INTUITION

VOLATILITY PREDICTION INTERVALS:

obtained by the diffusion limit of a multiplicative GARCH model

$$d \ln \sigma_t^2 = \left(\beta_0 + 2\beta_1 E(\ln |Z_t|) + (\beta_1 - 1) \ln \sigma_t^2 \right) dt + 2\beta_1 \sqrt{Var(\ln |Z_t|)} dW_t^*$$

- well-known distributional properties
- immediate update according to new information (**adaptivity**)

Synthetic risk indicator

Assessing *market feasibility*

putting together the two ingredients

3rd INTUITION

It requires to study when the realized volatility of the automatic asset manager is outside the Garch-based volatility prediction interval:

MANAGEMENT FAILURES

Synthetic risk indicator

3rd INTUITION

MANAGEMENT FAILURES:

Synthetic risk indicator

3rd INTUITION

MANAGEMENT FAILURES:

NOT ABNORMALITY

HOMOGENEITY

low number of failures

equal number of failures

Synthetic risk indicator

Solving for the optimal grid

NOT ABNORMALITY

&

HOMOGENEITY

$$\lambda = \left(\frac{\sigma_n}{\sigma_0} \right)^{\frac{1}{n}}$$

Unbundling and Probabilistic performance scenarios

! COMPLEX PRODUCT

The additional information to be supplemented must

be easy to understand for the average investor

capture efficiently all the main statistical characteristics of the probability distribution of the product

the unbundling represented by using a table is first level tool useful to appreciate the impact of the costs and the riskiness of the product

The unbundling exploits only the information contained in the first order moment of the probability distribution

Proposal 2: Unbundling the information content of the price

135

Unbundling and Probabilistic performance scenarios

! COMPLEX PRODUCT

The additional information to be supplemented must

be easy to understand for the average investor

capture efficiently all the main statistical characteristics of the probability distribution of the product

Proposal 3: Perform a reduction in granularity by implementing a partition of the probability distribution

Risk books

136

Unbundling and Probabilistic performance scenarios

! COMPLEX PRODUCT

Partition of the Probability distribution of the Complex Product with respect to the point of zero return

The assessment of the probability of recovering at least the amount paid for the product is of great significance for the investor.

Risk books

137

Unbundling and Probabilistic performance scenarios

! COMPLEX PRODUCT

Partition of the risk-neutral density of the Complex Product with respect to the point of zero return and to the two fixed positive thresholds α_1 and α_2

It is appropriate to explore further partitions of the macro-event “the final value of the investment is higher than the issue price” by performing a direct comparison with the final values of the risk-free asset.

Risk books

138

Unbundling and Probabilistic performance scenarios

! COMPLEX PRODUCT

Partition of the risk-neutral density of the Complex Product with respect to the point of zero return and to the two fixed positive thresholds α_1 and α_2

SCENARIOS	PROBABILITY	MEAN VALUES
The performance is <u>negative</u>	...	...
The performance is <u>positive but lower</u> than the risk-free asset	...	...
The performance is <u>positive and in line</u> with the risk-free asset	...	...
The performance is <u>positive and higher</u> than the risk-free asset	...	...

MEAN VALUES

$$E^R(S_T | S_T < 100) = \frac{1}{P(S_T < 100)} \int_{-\infty}^{100} x f_{S_T}(x) dx$$
$$E^R(S_T | 100 \leq S_T < \alpha_1) = \frac{1}{P(100 \leq S_T < \alpha_1)} \int_{100}^{\alpha_1} x f_{S_T}(x) dx$$
$$E^R(S_T | \alpha_1 \leq S_T < \alpha_2) = \frac{1}{P(\alpha_1 \leq S_T < \alpha_2)} \int_{\alpha_1}^{\alpha_2} x f_{S_T}(x) dx$$
$$E^R(S_T | S_T \geq \alpha_2) = \frac{1}{P(S_T \geq \alpha_2)} \int_{\alpha_2}^{+\infty} x f_{S_T}(x) dx$$

139

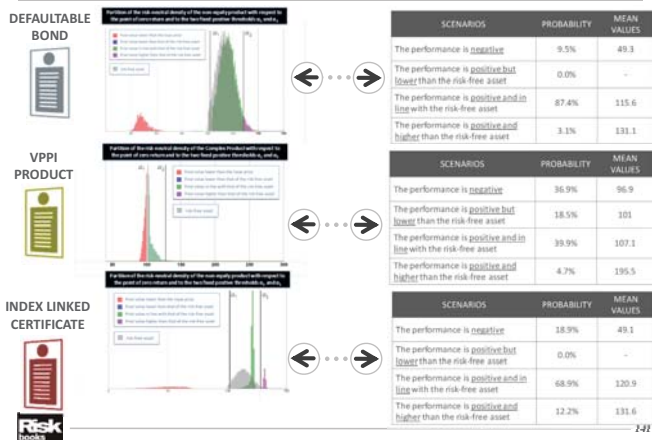

Unbundling and Probabilistic performance scenarios

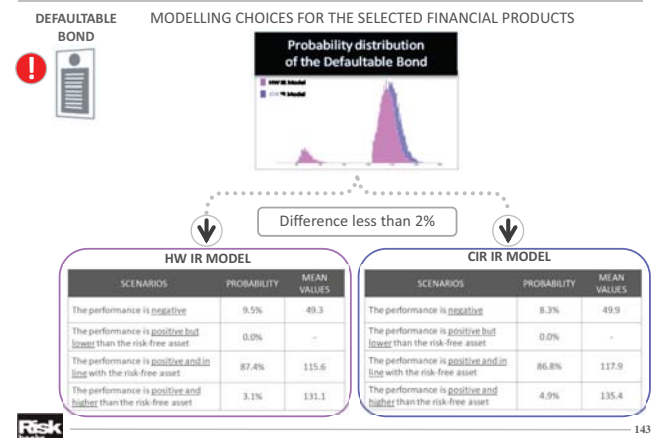

Benefits of this solution:

1. The reduction in granularity of the events determined by the partition involves only a very limited loss of information and the table, built by coupling for each scenario its risk-neutral probability and the associated mean value, is very easy to read;

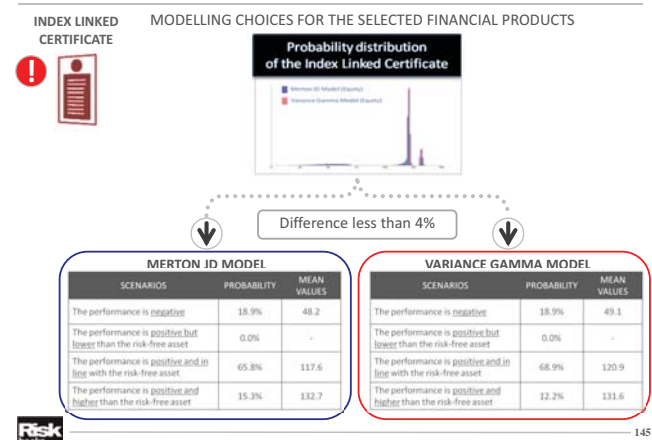

Unbundling and Probabilistic performance scenarios

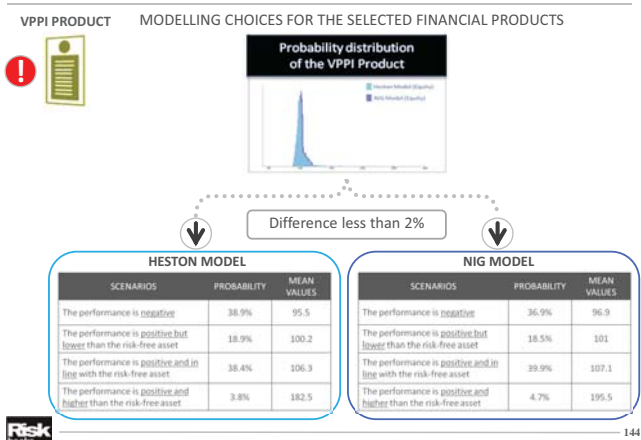

Unbundling and Probabilistic performance scenarios

Unbundling and Probabilistic performance scenarios

Unbundling and Probabilistic performance scenarios

Unbundling and Probabilistic performance scenarios

! COMPLEX PRODUCT

The additional information to be supplemented must

✓ be easy to understand for the average investor

✓ capture efficiently all the main statistical characteristics of the probability distribution of the product

the partition should be done by choosing events that have a strong financial meaning for the investor

the reduction in granularity mitigates in a significant way the model risk

Proposal 3: Perform a reduction in granularity by implementing a partition of the probability distribution

146

Unbundling and Probabilistic performance scenarios

Since there's a close one-to-one relationship between the two tables, the two sets of information can be easily coupled in an easy-to-read sheet

COMPLEX PRODUCT

147

Syllabus

- Preliminaries: the three pillars
- The recommended Investment horizon
- Synthetic risk indicator
- Unbundling and Probabilistic performance scenarios
- An Application of the methodology

Examples

VPPI PRODUCT

DESCRIPTION

VPPI technique is aimed at protecting the initial value of the financial investment over a specified time horizon and obtaining possible gains by limited exposure to the equity markets.

1st PILLAR

Financial investment table

(Price Unbundling)

A	Theoretical value of the Risk-Free component	90.1
B	Theoretical value of the Risky component	6.4
C = A + B	Fair value	96.5
D	Costs	3.5
E = C + D	Issue price	100

Table of the probabilistic performance scenarios

SCENARIOS	PROBABILITY	MEAN VALUES
The performance is <i>negative</i>	36.9%	96.9
The performance is <i>positive but lower</i> than the risk-free asset	18.5%	101
The performance is <i>positive and in line</i> with the risk-free asset	39.9%	107.1
The performance is <i>positive and higher</i> than the risk-free asset	4.7%	115.5

2nd PILLAR

Degree of Risk: Medium

3rd PILLAR

Recommended investment time horizon: 5 years
